

# Information And Database Management Systems (CSE 227)

Vikas Bajpai

# Acknowledgements

Many slides of this presentation are from  
“Fundamentals of Database Systems, by  
Elmasri, Navathe”.

# Course Content:

- **Introduction**

- Introduction and evolution of database systems; Data Models; Three schema architectures; Data Independence

- **Conceptual Modeling and Database Design**

- ER Model – Entity, Attributes, Relationship, Structural constraints; EER Model – Generalization, Specialization, Union types

- **Relational Data Model and Relational Algebra**
  - Relational model concepts; Constraints; Entity and referential integrity; Mapping conceptual schema to relational schema; Relational algebra – Unary, Binary and set theoretic operations
- **Database Design and Normalization**
  - Relational database design; Functional dependency, Normal forms; Decomposition; Properties of decomposition – Attribute preservation, Dependency preservation, Lossless join; Keys; Closure; Minimal cover; Normalization; Denormalization

- **File structures, Indexing, and Hashing**
  - Secondary storage devices; File records; Unordered file; Ordered file, Hashed file; Indexes; Dense and Sparse index; Single-level and Multi-level indexes; Multi-level indexing using B-tree and B<sup>+</sup>-tree
- **Transaction Processing, Concurrency Control, and Recovery**
  - Transaction and system concepts; ACID properties; Serializability; Concurrency control techniques – Two phase locking, Timestamp ordering, Multiversion techniques; Deadlock and starvation; Recovery concepts; Immediate update, Deferred update; Write-ahead logging; Checkpointing; ARIES recovery algorithm

- **Advanced Topics**

- Introduction to distributed, parallel and object-oriented databases; Basic concepts of Data warehouse; Approaches for managing large volume of data

# Evaluation Criteria:

Component	Weightage
Lab	25%
Continuous evaluation (Quiz/ Assignment/Attendance)	10%
Midterm	25%
Final Examination	40%
<b>Total</b>	<b>100%</b>

# Text Book(s):

- R. Elmasri and S. Navathe, *Fundamentals of Database Systems*, Addison-Wesley, 6<sup>th</sup> ed., 2011
- Silberschatz, H. Korth, and S. Sudarshan, *Database System Concepts*, McGraw-Hill.

# Reference Book(s):

- R. Ramakrishnan, *Database Management Systems*, WCB/McGraw-Hill.
- C.J. Date, *An Introduction to Database Systems*, Pearson, 8<sup>th</sup> ed.

# Data:

- information in raw or unorganized form.
- facts and statistics collected together for reference or analysis.

# Database:

- Is an **organized** collection of data. ←
- Collection of **related** data.
- Collection of schemas, tables, queries, reports, views etc. etc.

# Database:

# Databases these days:

- Used daily: 😊
  - Facebook
    - Posts
    - Likes
  - Twitter
    - Tweets
  - Online shopping
    - amazon.com
    - flipcart.com

# Database Management System (DBMS):

- A collection of programs that enables users to **create** and **maintain** a database.
- A general purpose software system that facilitates the process of:

- Defining
- Constructing
- Manipulating
- Sharing

**DBMS Functionalities**

databases among various users and applications.

# DBMS Functionalities:

- **Define** a database : in terms of data types, structures and constraints
- **Construct** or Load the Database on a secondary storage medium
- **Manipulating** the database : querying, generating reports, insertions, deletions and modifications to its content
- **Concurrent Processing** and **Sharing** by a set of users and programs – yet, keeping all data valid and consistent

# Example of a simple database

# DBMS Functionalities:

## Other features:

- **Protection** or **Security** measures to prevent unauthorized access
- “**Active**” processing to take internal actions on data
- **Presentation** and **Visualization** of data
- **Maintenance** of the database and associated programs over the lifetime of the database application

# Simplified database system environment:

**Source:** Rameez Elmasri and Shamkant B. Navathe

# Database approach vs file processing approach:

- **Self describing** nature of a database system.
- Insulation between programs and data, and data abstraction.
- Support of **multiple views** of data.
- **Sharing** of data and **multiuser transaction processing**.
  - Allowing concurrent users for retrieval & updating
  - Concurrency control
  - Ensuring complete transaction
  - OLTP (online transaction processing)

# A Sample Data

# Data Abstraction:

- A **data model** is used to **hide** storage **details** and present the users with a **conceptual view** of the database.
- Programs refer to the **data model constructs** rather than data storage details

# Database Users:

- Users may be divided into:
  - Those who **actually use** and **control** the database content, (called **“Actors on the Scene”**), and
  - Those who design and develop the DBMS software and related tools, and the computer systems operators (called **“Workers Behind the Scene”**).

# 1. Actors on the scene:

## 1. Database Administrators

- Responsible for **authorizing access** to the database, for coordinating and monitoring its use, **acquiring software** and **hardware** resources, controlling its use and **monitoring** efficiency of operations.

## 2. Database Designers

- Responsible to **define** the content, the **structure**, the **constraints**, and **functions** or **transactions** against the database. They **must communicate** with the end-users and understand their needs.

**Contd...**

# 1. Actors on the scene:

3. End Users : They use the data for **queries**, **reports** and some of them update the database content. End-users can be categorized into:

- a. **Casual end users**: access database occasionally
- b. **Naive or Parametric end users**: they make up a large section of the end-user population.
  - They use previously well-defined functions in the form of “canned transactions” against the database.
  - Users of Mobile Apps mostly fall in this category
  - Bank-tellers or reservation clerks are parametric users who do this activity for an entire shift of operations.
  - Social Media Users post and read information from websites

**Contd...**

# 1. Actors on the scene:

## c. Sophisticated end users:

- These include business analysts, scientists, engineers, others thoroughly familiar with the system capabilities.
- Many use tools in the form of software packages that work closely with the stored database.

## d. Stand-alone users:

- Mostly maintain personal databases using ready-to-use packaged applications.
- An example is the user of a tax program that creates its own internal database.
- Another example is a user that maintains a database of personal photos and videos.

**Contd...**

# 1. Actors on the scene:

4. System Analysts and Application Programmers (S/W Engineers): This category currently accounts for a very large proportion of the IT work force.

- a. **System Analysts:** They understand the user requirements of naïve and sophisticated users and design applications including canned transactions to meet those requirements.
- b. **Application Programmers:** Implement the specifications developed by analysts and test and debug them before deployment.
- c. **Business Analysts:** There is an increasing need for such people who can analyze vast amounts of business data and real-time data (“Big Data”) for better decision making related to planning, advertising, marketing etc.

## 2. Workers behind the scene:

1. **DBMS system designers and implementers:** Design and implement DBMS packages in the form of modules and interfaces and test and debug them. The DBMS must interface with applications, language compilers, operating system components, etc.
2. **Tool developers:** Design and implement software systems called tools for modeling and designing databases, performance monitoring, prototyping, test data generation, user interface creation, simulation etc. that facilitate building of applications and allow using database effectively.
3. **Operators and maintenance personnel:** They manage the actual running and maintenance of the database system hardware and software environment.

# Advantages of using DBMS approach:

- Controlling redundancy
- Restricting unauthorized access
- Providing persistent storage for program objects
- Providing storage structures for efficient query processing
- Providing backup and recovery
- Providing multiple user interfaces
- Representing complex relationships among data

Contd...

# Advantages of using DBMS approach:

- Enforcing integrity constraints
- Permitting inferencing and actions using rules
- Additional implications of using database approach:
  - Potential for enforcing standards
  - Reduced application development time
  - Flexibility
  - Availability of up-to-date information

# When not to use a DBMS:

## Overhead cost of using DBMS because of:

- High initial investment in hardware, software and training
- The generality that a DBMS provides for defining and processing data.
- Overhead for providing security, concurrency control, recovery and integrity functions.

# When not to use a DBMS:

If the database designers and DBA do not properly design the database or if the database systems are not implemented properly:

- The database and applications are simple, well defined and not expected to change.
- There are stringent real time requirements for some programs that may not be met because of DBMS overhead.
- Multiple-user access to data is not required.

# View of Data:

- View is a **single table**, **derived** from other tables. These other tables could be **base tables** or **previously defined views**.
- A view doesn't exist in physical form, it is considered as a **virtual table**.

**In other words:**

- View logically represents **subset** of **data** from one or more tables.

# Why to use View:

- To **restrict** database access
- To **make** complex queries easy
- To allow **data independence**
- To present **different views** of same data

# Data Abstraction:

- A **data model** is used to **hide** storage **details** and present the users with a **conceptual view** of the database.
- Programs refer to the **data model constructs** rather than data storage details

# Data Abstraction:

- For a system to be usable, it must **retrieve data efficiently**.
- Developers hide the complexity from users through several **levels of abstraction**.

# Levels of Data Abstraction:

1. **Physical Level (Internal):** The lowest level of abstraction describes how the data are actually stored. The physical level describes complex low level data structures in detail.
2. **Logical Level (Conceptual):** It describes 'what data are stored in database' and what relationship exists among those data.
3. **View Level (External):** The highest level of abstraction which describes only part of entire database.

# Data Abstraction:

What data users and application programs see ?

What data is stored ?

describe data properties such as data semantics, data relationships

How data is actually stored ?

e.g. are we using disks ? Which file system ?

# Database Instances/ Database state:

- The collection of information stored in the database at a particular moment is called an **instance** of a database.

# Database Instances/ Database state:

- Database State:

- Refers to the **content** of a database at a moment in time.

- Initial Database State:

- Refers to the database state when it **is initially loaded** into the system.

- Valid State:

- A state that satisfies the **structure** and **constraints** of the database.

# Example of a database state:

# Database Schemas:

- The overall design of the database is called the **database schema**.

**In other words:**

- The description of a database is called the **database schema**. Includes descriptions of the **database structure**, **data types**, and the **constraints** on the database.

# Example of a Database Schema:

# Data Model:

- A collection of concepts, used to describe the **structure\*** of a database.
- It provides the necessary means to achieve abstraction.
- \* **Structure** of a database means **data types**, **relationships** and **constraints** that should hold for the data.

# Categories of data models:

1. High level or conceptual data models
2. Low level or physical data models
3. Representation or implementation data models
4. Self-Describing Data Models

# Categories of Data Models:

## 1. High level or conceptual data models:

- Provide concepts that are close to the way many users perceive data.
  - (Also called ***entity-based*** or ***object-based*** data models.)

## 2. Low level or physical data models:

- Provide concepts that describe details of how data is stored in the computer. These are usually specified in an ad-hoc manner through DBMS design and administration manuals

## 3. Representation or implementation data models:

- Provide concepts that fall between the above two, used by many commercial DBMS implementations (e.g. relational data models used in many commercial systems).

## 4. Self-Describing Data Models:

- Combine the description of data with the data values. Examples include XML, key-value stores and some NOSQL systems.

# Three Schema Architecture:

- Goal is to separate “user application” and “physical database”.
- Not explicitly used in commercial DBMS products, but has been useful in explaining database system organization
- Three schema architecture defines DBMS schemas at three levels levels are:
  1. Internal schema
  2. Conceptual schema
  3. External schema

# Three Schema Architecture:

DBMS schemas at three levels are:

1. **Internal schema** at the internal level to describe physical storage structures and access paths (e.g indexes).
  - Typically uses a physical data model.
2. **Conceptual schema** at the conceptual level to describe the **structure** and **constraints** for the whole database for a community of users.
  - Uses a conceptual or an implementation data model.
3. **External schemas** at the external level to describe the various user views.
  - Usually uses the same data model as the conceptual schema.

# Three Schema Architecture:

# Three-Schema Architecture:

- Mappings among schema levels are needed to transform requests and data.
  - **Programs** refer to an **external schema**, and are mapped by the DBMS to the **internal schema** for execution.
  - Data extracted from the internal DBMS level is reformatted to match the user's external view (e.g. formatting the results of an SQL query for display in a Web page)

# Data Independence:

- Data independence is the **capacity** to **change** the **schema** at one level of a database system without any change in the schema at the **next higher level**. Only the **mapping** between the two levels is **changed**.
- Two types of Data Independence:
  1. Logical Data Independence
  2. Physical Data Independence

# 1. Logical Data Independence:

- It is the capacity to change **conceptual schema** without having any change in **external schema**.
- We may change conceptual schema to **expand** the database, to **change** the **constraints**, or to **reduce** the database.
- **After conceptual schema undergoes a logical reorganization, application program that refer the external schema must work as before.**

## 2. Physical Data Independence:

- It is the capacity to change the **internal schema** without having any change in the **conceptual schema**. Hence the external schema need not be changed as well .
- **Change to the internal schema may be needed because some physical files had to be reorganized.**

# Database Languages:

1. Data-definition Language (DDL)
2. Data-manipulation Language (DML)
  - a. Procedural DMLs
  - b. Declarative DMLS (Non Procedural DML)

# 1. Data-definition Language (DDL):

- DDL is a set of definitions which specify a **database schema**.
- DDL is used by DBA and database designers to define all schemas.

Eg. -> create table ACCOUNT (name char(10),  
balance integer)

Execution of above DDL statement creates ACCOUNT table plus updates a special set of tables called **Data Dictionary\*** or **Data Directory**.

## 2. Data-manipulation Language (DML):

- DML is a language that enables users to **access** or **manipulate** data as organized by appropriate data model.
- Two types of DML:
  - a. **Procedural DMLs**-require a user to specify what data are needed and how to get those data.
  - b. **Declarative DMLs (Non-Procedural)**- require a user to specify what data are needed without specifying how to get those data.

# Data Manipulation Language is:

- The **retrieval** of information stored in database.
- The **insertion** of information into the database.
- The **deletion** of information from the database.
- The **modification** of information stored in database.

# DBMS Programming Language Interfaces:

- Programmer interfaces for embedding DML in a programming languages:
  - **Embedded Approach:** e.g. embedded SQL (for C, C++, etc.), SQLJ (for Java)
  - **Procedure Call Approach:** e.g. JDBC for Java, ODBC (Open Database Connectivity) for other programming languages as API's (application programming interfaces)
  - **Database Programming Language Approach:** e.g. ORACLE has PL/SQL, a programming language based on SQL; language incorporates SQL and its data types as integral components
  - **Scripting Languages:** PHP (client-side scripting) and Python (server-side scripting) are used to write database programs.

# User-Friendly DBMS Interfaces:

- **Menu-based** (Web-based), popular for browsing on the web
- **Forms-based**, designed for naïve users used to filling in entries on a form
- **Graphics-based**
  - Point and Click, Drag and Drop, etc.
  - Specifying a query on a schema diagram
- **Natural language**: requests in written English
- **Combinations of the above**:
  - For example, both menus and forms used extensively in Web database interfaces

# Other DBMS Interfaces:

- **Natural language**: free text as a query
- **Speech** : Input query and Output response
- **Web Browser with keyword search**
- **Parametric interfaces**, e.g., bank tellers using function keys.
- **Interfaces for the DBA:**
  - Creating user accounts, granting authorizations
  - Setting system parameters
  - Changing schemas or access paths

# Database System Utilities:

To perform certain functions such as:

- Loading data stored in files into a database. Includes data conversion tools.
- Backing up the database periodically on tape.
- Reorganizing database file structures.
- Performance monitoring utilities.
- Report generation utilities.
- Other functions, such as sorting, user monitoring, data compression, etc.

# Other Tools:

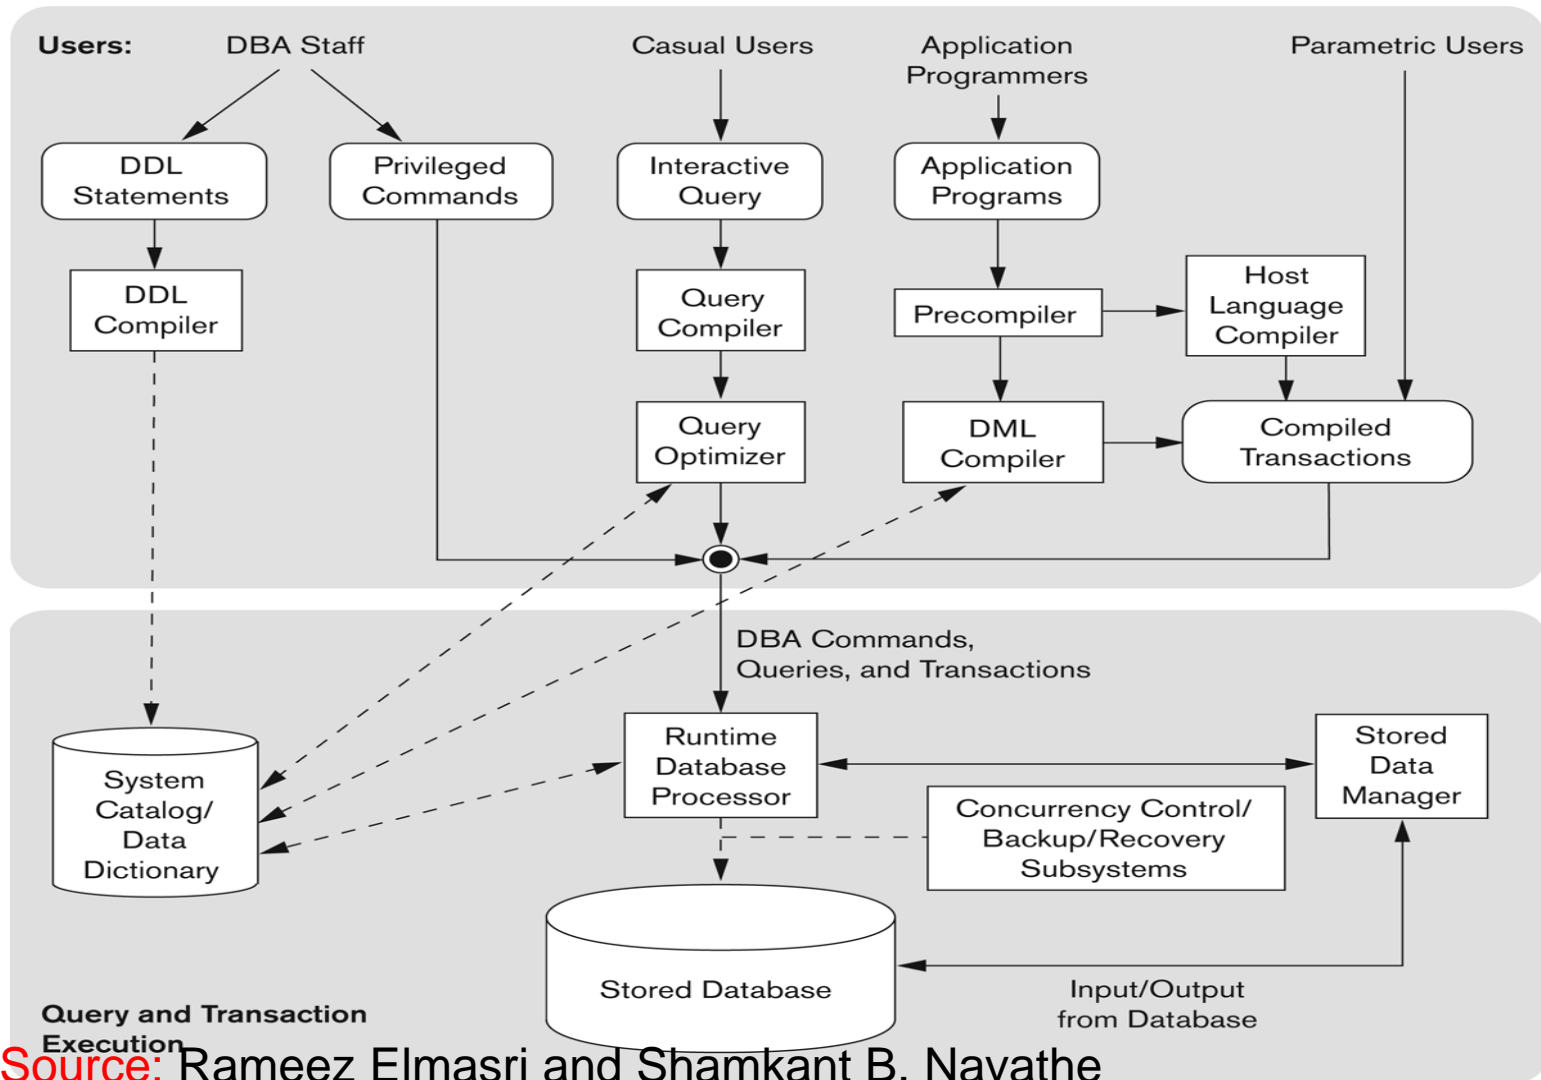

## Data dictionary / repository:

- Used to store **schema descriptions** and other information such as **design decisions**, application program descriptions, user information, usage standards, etc.
- **Active data dictionary** is accessed by DBMS software and users/DBA.
- **Passive data dictionary** is accessed by users/DBA only.

# Other Tools:

- Application Development Environments and CASE (computer-aided software engineering) tools:
- Examples:
  - PowerBuilder (Sybase)
  - JBuilder (Borland)
  - JDeveloper 10G (Oracle)

# DBMS component modules and their interactions:

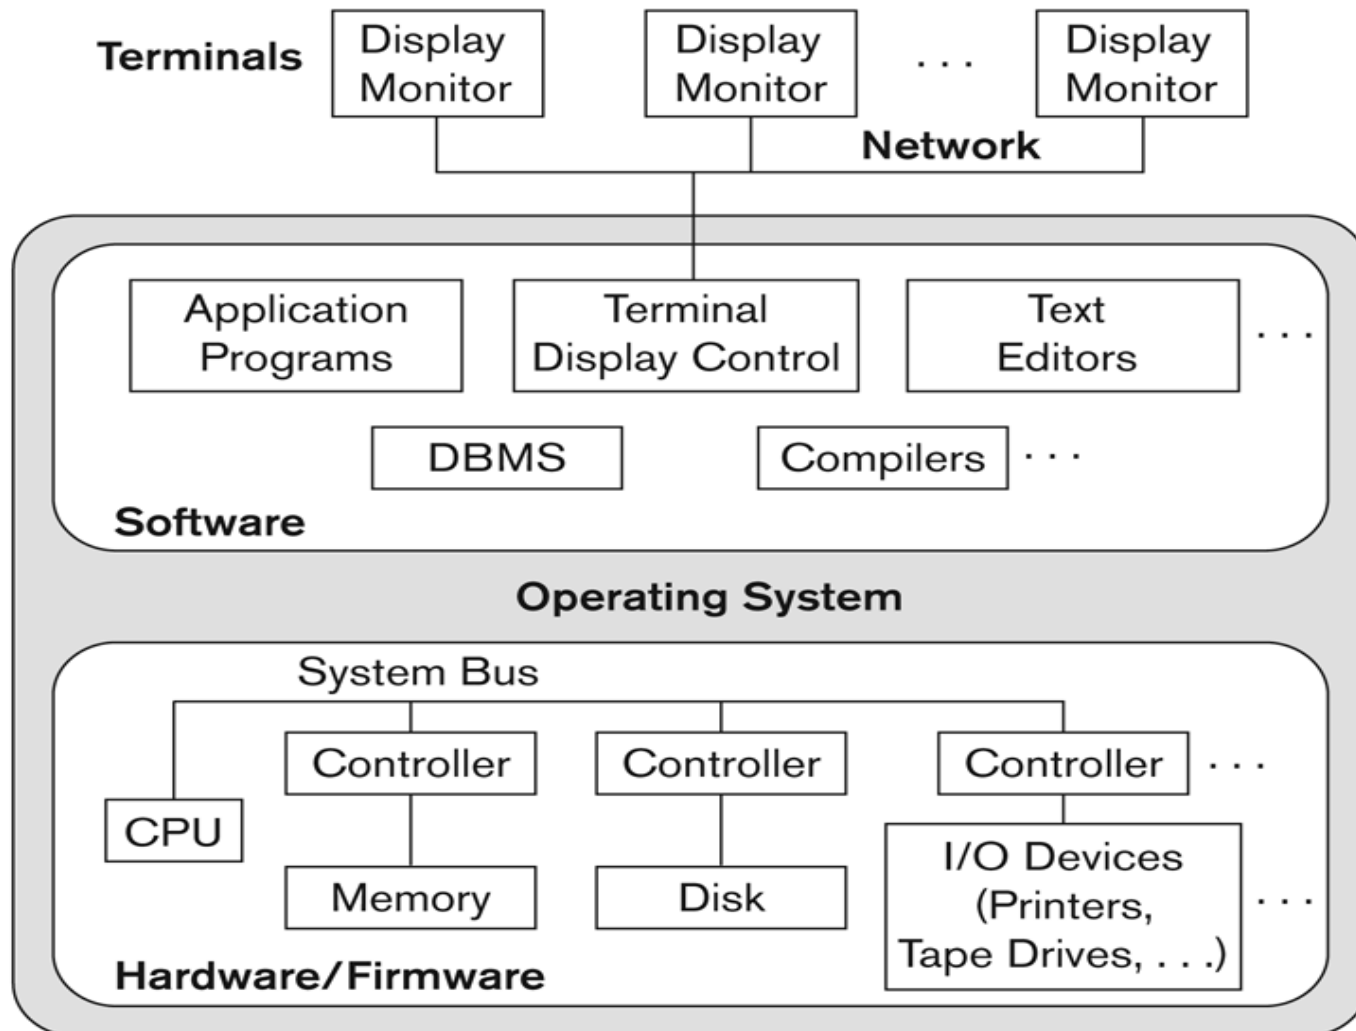

# Centralized DBMS Architectures:

- Combines **everything into single system** including- DBMS software, hardware, application programs, and user interface processing software.
- User can still connect through a remote terminal – however, all processing is done at centralized site.

# Centralized DBMS Architectures:

Source: Rameez Elmasri and Shamkant B. Navathe

# Client Server DBMS Architecture:

- **Client Module:** handles user interaction and provides the user friendly interfaces such as forms or menu based GUIs
- **Server Module:** handles data storage, access, search and other functions.

# Three Tier Client-Server Architecture

- Common for Web applications
- Intermediate Layer called Application Server or Web Server:
  - Stores the web connectivity software and the business logic part of the application used to access the corresponding data from the database server
  - Acts like a conduit for sending partially processed data between the database server and the client.
- Three-tier Architecture Can Enhance Security:
  - Database server only accessible via middle tier
  - Clients cannot directly access database server
  - Clients contain user interfaces and Web browsers
  - The client is typically a PC or a mobile device connected to the Web

# Three-tier client-server architecture

# A Database with Multiple Tables

# DBMS at a Glance
